# Time standards

Astronomische Zeit (AT)	basiert auf der gleichförmigen Bewegung von Himmelskörpern
Physikalische Zeit (PT)	basiert auf periodischen physikalischen Prozessen (Schwingungen)
Sonnendurchlauf:	Höchster Punkt der Sonne während eines Tages
Sonnentag:	Intervall zwischen zwei aufeinanderfolgenden Sonnendurchläufen
Sonnensekunde:	Der 1 / 86400 Teil eines Sonnentages
Mittlere Sonnensekunde:	Sonnensekunde gemittelt über eine große Anzahl von Sonnentagen
Zeitzonen:	Erster Zeitstandard (1820) basiert auf mittlerer Sonnensekunde Gebiete für die dieselbe Zeit festgelegt ist. 1884 wird die Welt in 24 Zeitzonen aufgeteilt. Die Zeitzonen unterscheiden sich von UT (GMT) ganzzahlig um jeweils 1 Stunde.
UT                   (AT, 1833)	Universal Time (UT) Mittlere Sonnenzeit, gemessen am Greenwich 0-Meridian (GMT). Basiert auf der mittleren Länge eines Sonnentags, d.h. auf der Erdrotation
ET                   (AT, 1955)	Ephimeridenzeit (ET), basiert auf der Umlaufzeit der Erde um die Sonne. Harold Spencer Jones stellte 1939 fest, daß die Rotation der Erde variiert, die Umlaufzeit um die Sonne nicht. 1 Sekunde der ET wird festgelegt als der 1/31.566.925,9747 Teil des tropischen Jahres, das am Mittag des 1. Januars 1900 begann. (Tropische Jahr: Periode zwischen zwei aufeinanderfolgenden Durchläufen der Sonne durch den Himmelsäquator in derselben Richtung.)
UT0                  (AT, 1960)	Zeit, basierend auf den lokalen Beobachtungen verschiedener, über die Erde verteilter Observatorien.
UT1                  (AT, 1960)	Zeit, basierend auf der Koordination der verschiedenen UT0-Zeiten (Mittlung).
UT2                  (AT, 1960)	Nochmals, auf empirischer Basis korrigierte UT1-Zeit.
TAI                  (PT, 1961)	Temps Atomique International (TAI) basiert auf mehreren koordinierten Cäsium-Uhren. Fortlaufende Zeitzählung, beginnend mit dem 1. Januar 1958 0 Uhr UT2-Zeit (daher konsistent mit UT2).
UTC                  (PT, 1972)	Universal Time Coordinated (UTC) basiert auf TAI, wird aber ständig an UT2 angepaßt. Immer wenn UTC und UT2 mehr als 800 ms auseinander gedriftet sind, wird eine "Schaltsekunde" eingefügt. UTC beginnt am 1. Januar 1972. Seit dieser Zeit sind (bis 1992) 15 Schaltsekunden eingefügt worden. UTC ist damit eine an AT angepaßte physikalische Zeit. Genauigkeit: ca. 1 Sek / 300000 Jahre

## World wide, standardized time reference : *Universal Time Coordinated (UTC)*

---

**distributed by:**

- land-based radio stations (0,1-10 msec)
- GPS - *Global Positioning System*
- GEOS - *Geostationary Environmental Operational Satellites*

**Time base in distributed systems:**

- a (single) UTC-based reference clock
- local clocks
- algorithms for clock synchronization

**Correspondence to perfect time is dependent on:**

- precision of the time signal
- distance to sender
- atmospheric conditions
- drift of local clocks
- predictability of network latencies (**steadiness and tightness**)
- the synchronization algorithm

# Physical model of time

**Assumption: Existence of a uniform sequence of events suitable to represent a time reference**

## Properties:

**Equivalence:** All time stamps are equivalent in the sense that there is a linear formula converting a timestamp into another one.

**Linearity:** The conversion formulas are linear.  
Different timestamps can be related by a proportional factor.

**Causality:  
(potential)** Time is aligned according to an order of events which are related in a before/after relationship.

**Reversal:** Physical processes in general cannot be reversed.

**Homogeneity:** Time flow is uniform and does not contain holes.

# Relation between internal and external time

---

To measure the occurrence of events in a system in the metric of the external physical time (e.g. TAI), there must be an internal representation of the physical time.

**Internal physical time:** Internal time reference that approximates the external physical time. All events are ordered in the global flow of time. The before/after relation between events is determined according to the internal time. Causally independent events are also temporally ordered. Given two events  $e_1$  and  $e_2$  at time  $t_{e1}$  and  $t_{e2}$  respectively. If on an internal time scale  $t_{e1} \leq t_{e2}$  holds, this must also hold on an external time scale.

**Internal synchronization:** Synchronization of internal clocks .

**External Synchronization:** Synchronization to the external physical time.

# Physical Clocks

---

**Physical clock:**

Time reference that is based on periodic physical processes like oszillations of a pendulum, a cristall or an atom to measure the progression of time.

**Characterization of physical clocks:**

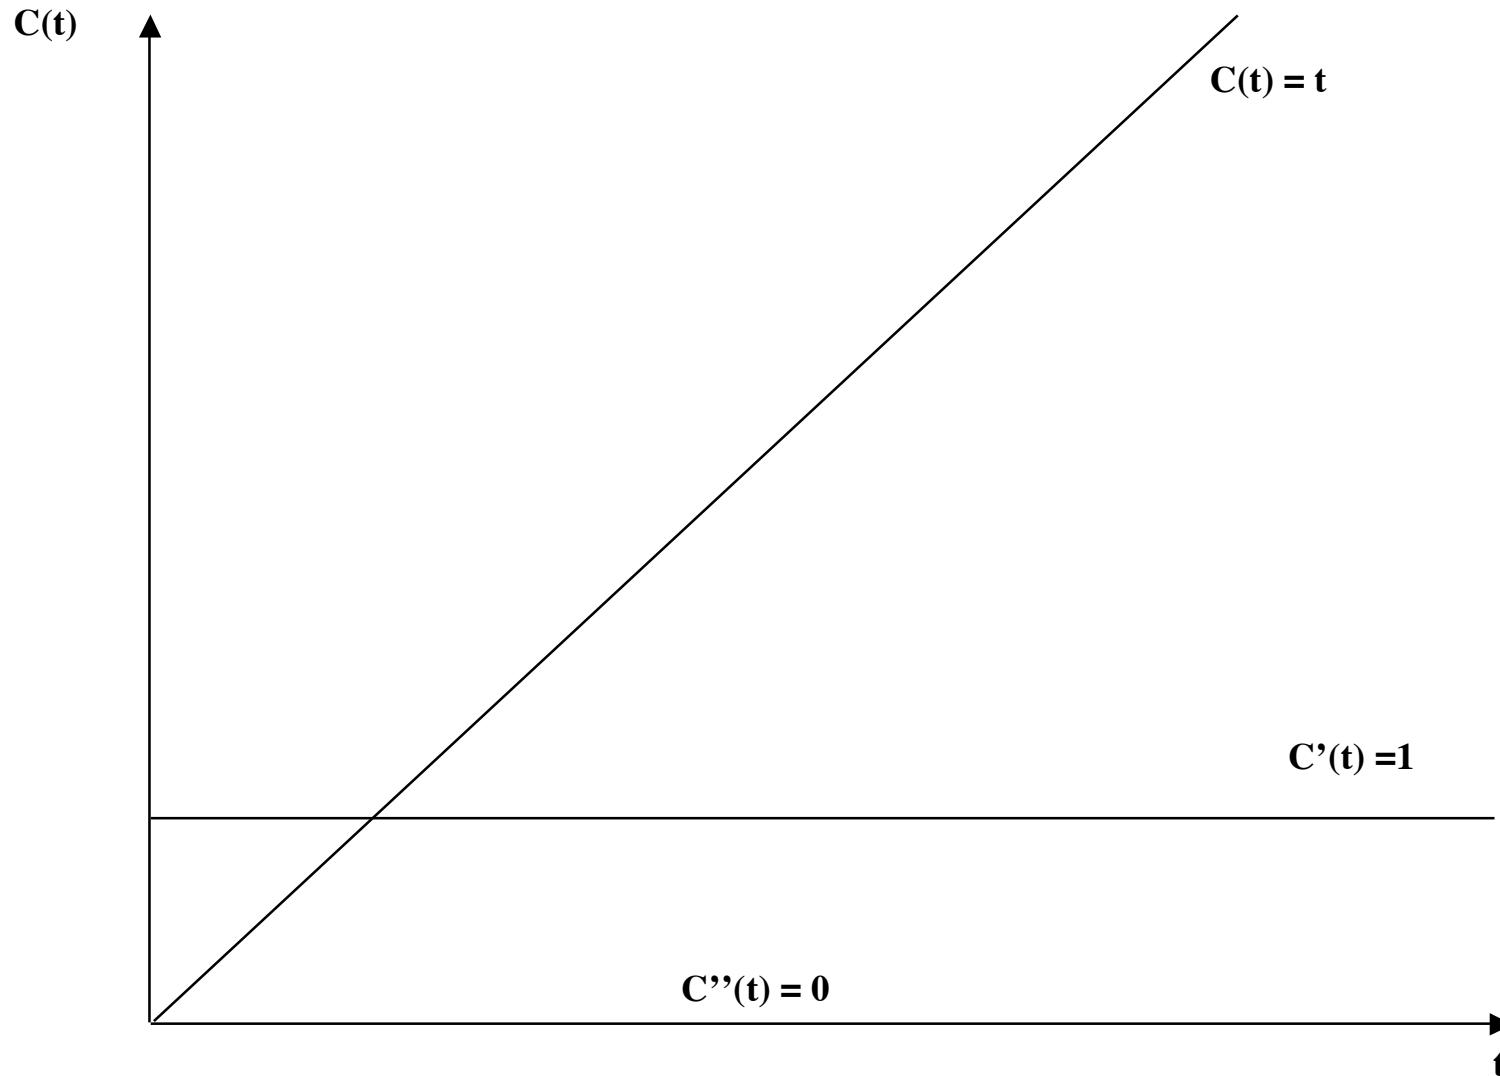

**Frequency/Rate:**  $f$  Number of periodic events per time frame. (oszillations, clock pulses)  
**Metric:** Hz, KHz, MHz, GHz, . . .

**Period**  $p=1/f$  Time interval between two consecutive periodic events.  
**Metric:** sec, ms,  $\mu$ s, ns . .

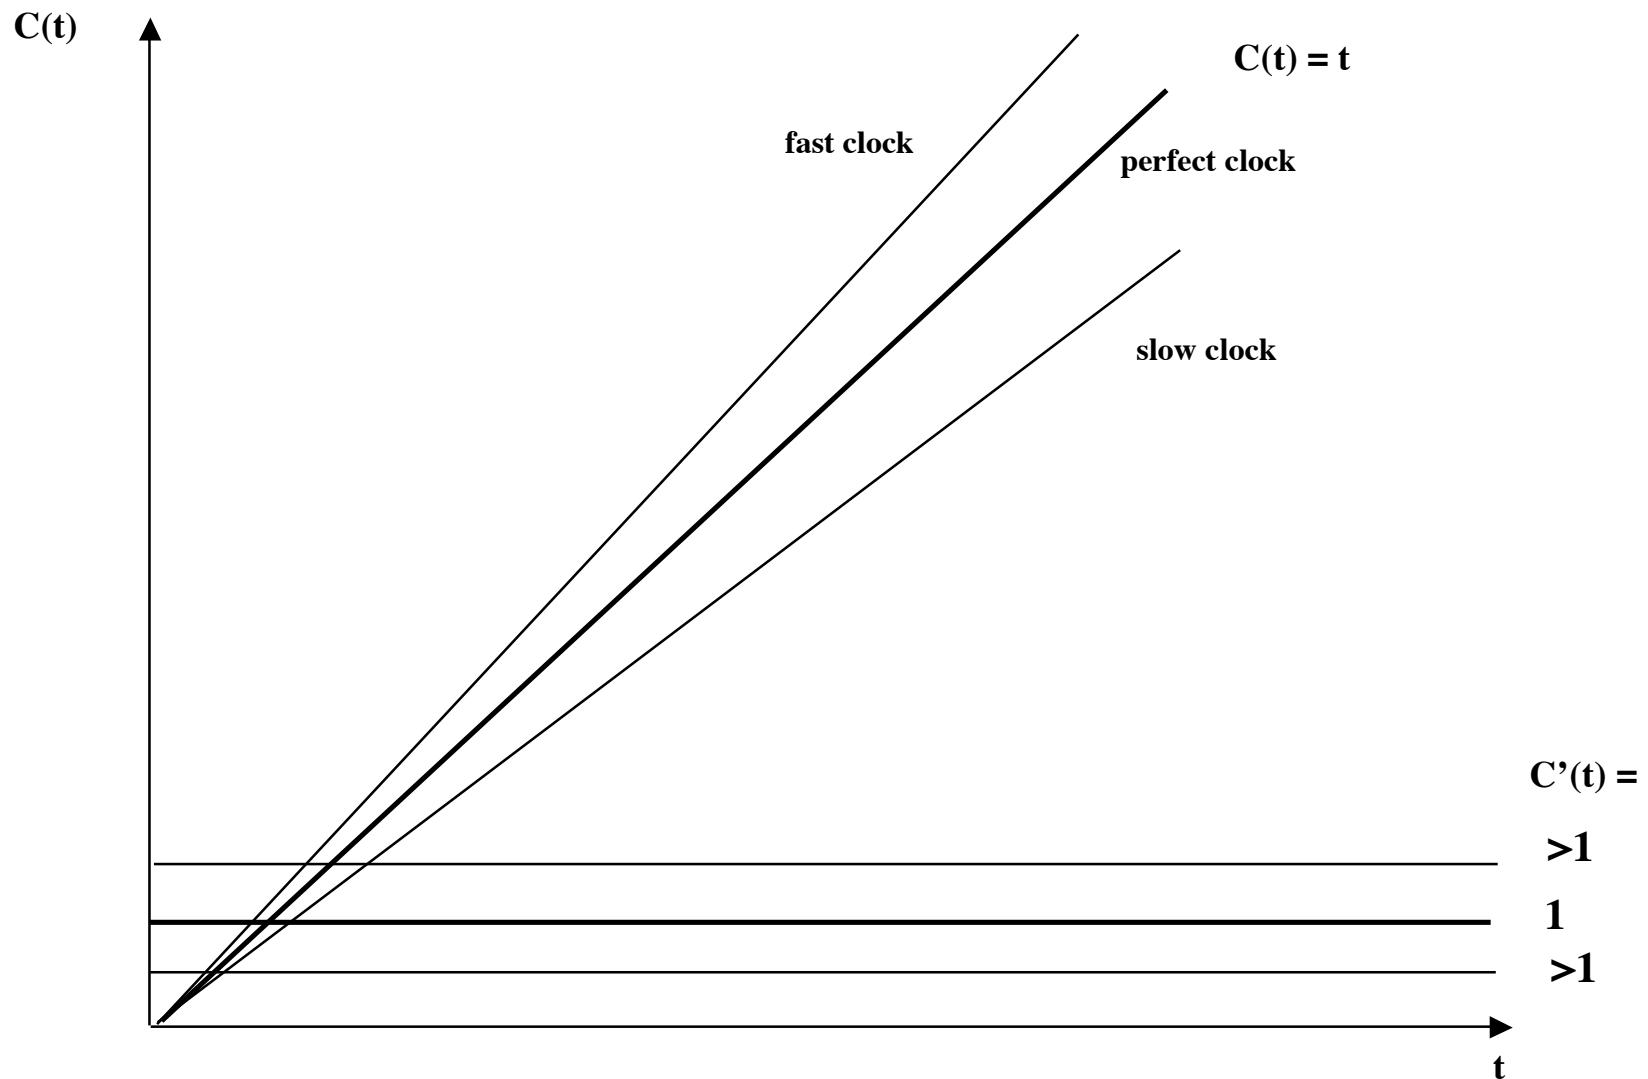

**Granularity:**  $g$  time interval between two clock pulses (corresponds to a period).  
Can only be determined by a clock of higher granularity. The garnularity determines the lower bound of the temporal distance beween two events that are not recognized as simultaneous events.  
**Metric:** sec, ms,  $\mu$ s, ns . .

# The perfect Clock

# Clock with constant Drift Rate

# Terminology

---

Let  $C(t)$  be the function that maps the time instance  $t$  of the reference time to the internal clock.

**Def. 1:**

a clock is a reference clock or perfect clock if :  $\forall t: C(t) = t$

**Def. 2:**

a clock is correct at time  $t_0$ , if  $C(t_0) = t_0$  is satisfied.

**Def. 3:**

a clock rate is perfect at  $t_0$ , if at  $t_0: C'(t) = 1$  ( $dC(t) / dt = 1$ )

$C'(t)$  denotes the (rate) stability of a clock.

We consider 3 cases:

$dC/dt > 1$ : *fast clock*

$dC/dt = 1$ : *perfect clock*,

$dC/dt < 1$ : *slow clock*

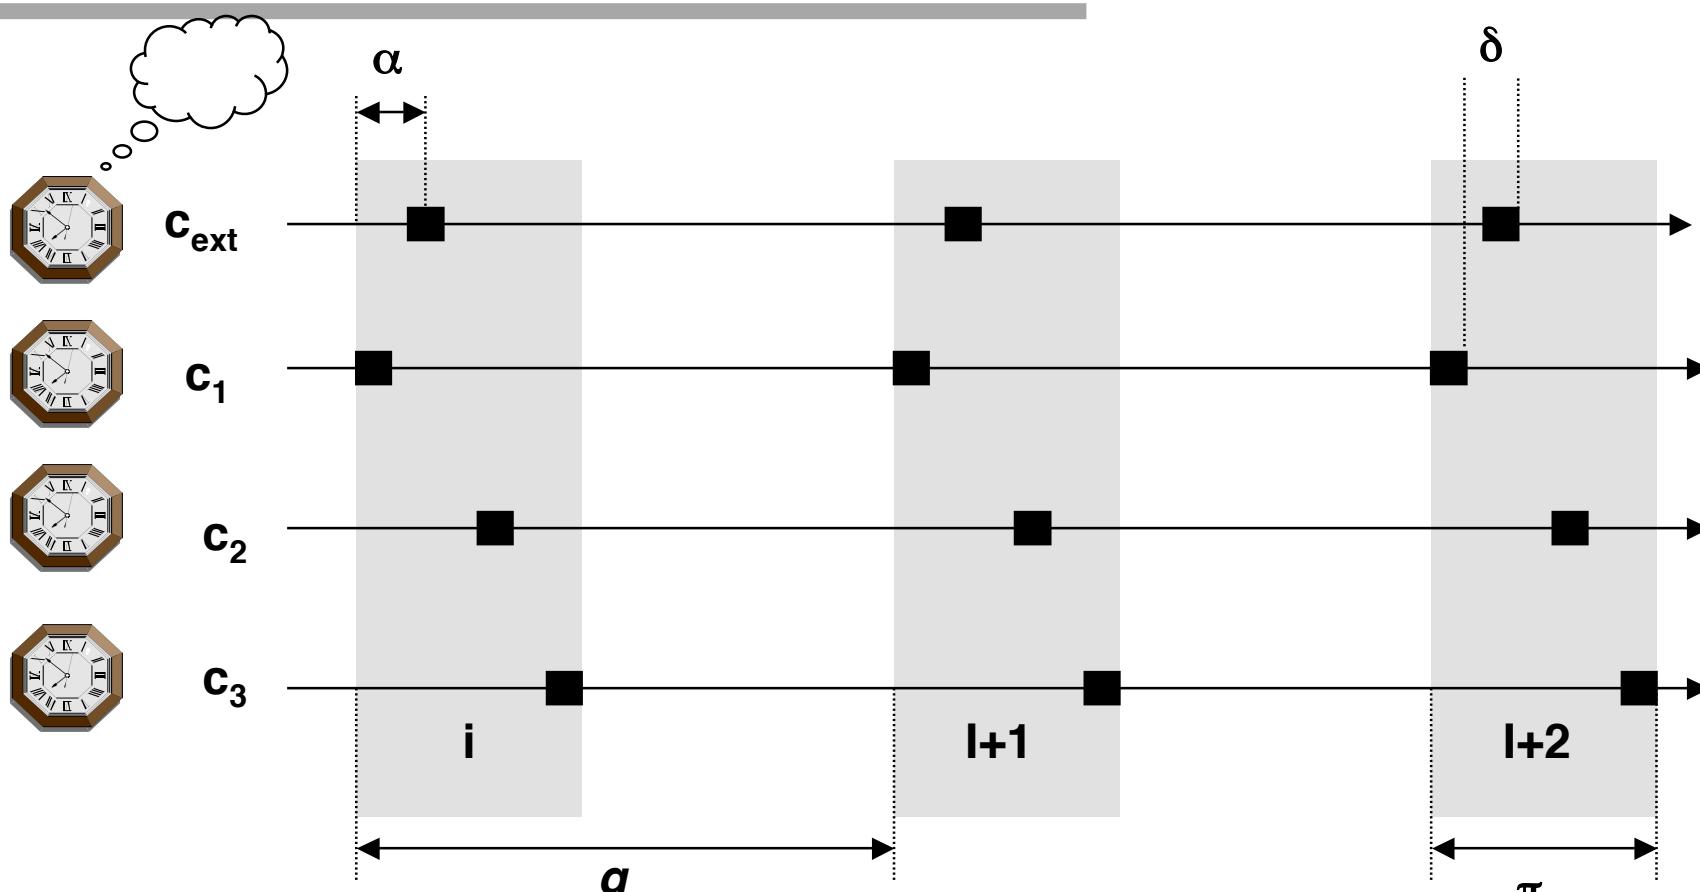

**Drift(rate)  $r$  :** deviation of the clock/time

The drift is assumed to be bounded by:

$$1-\rho \leq dC/dt \leq 1+\rho$$

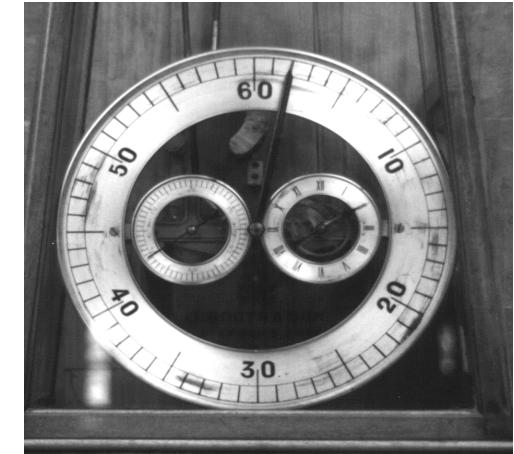

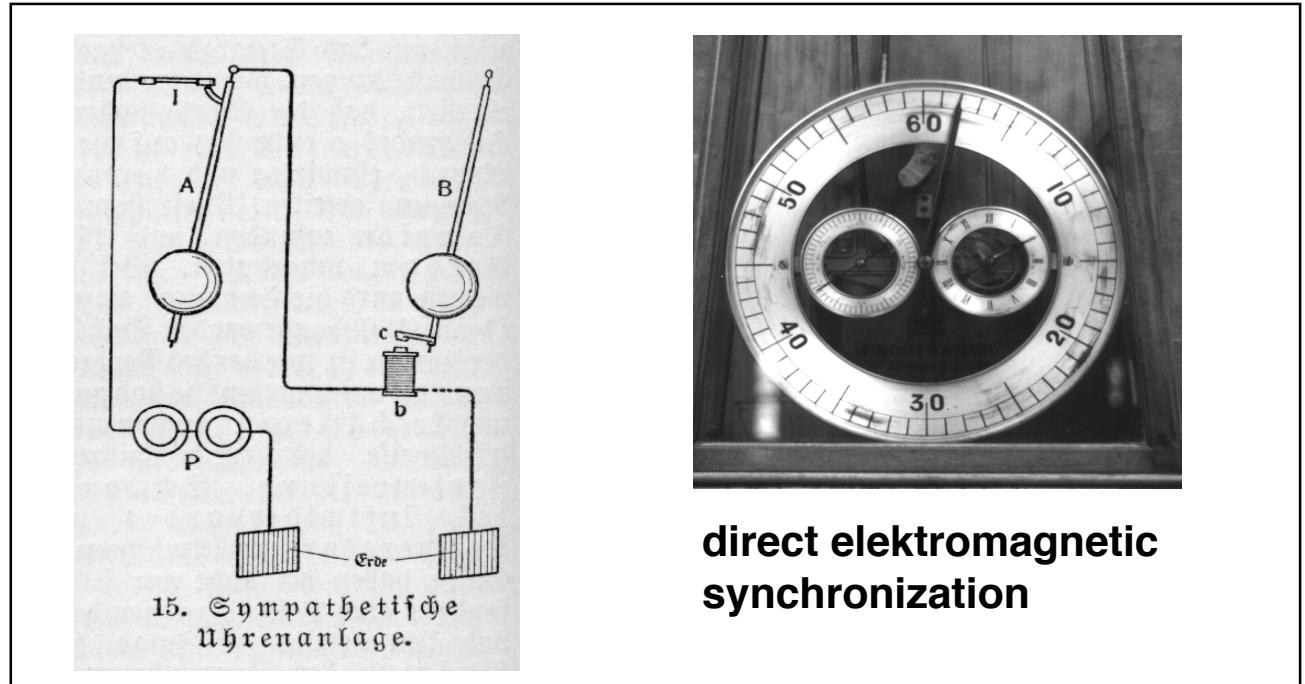

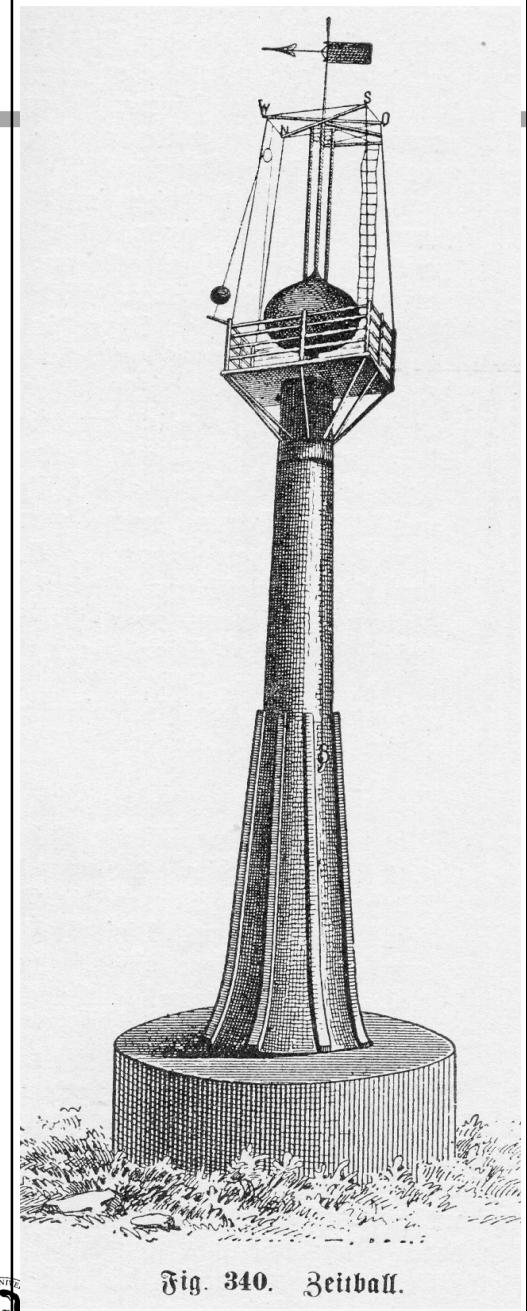

# Relation between the main distributed clock parameters

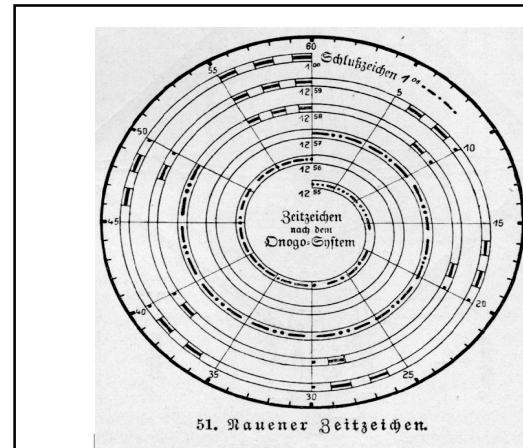

**$\alpha$  : accuracy**  
 **$\pi$  : precision**  
 **$g$  : granularity**  
 **$\delta$ : offset**

# Clock Synchronization

time signal of radio-based synchronization

# Synchrony between Clocks

Two clocks  $c_i$  and  $c_j$  are synchronous at time T, if:

$$|c_i(T) - c_j(T)| < \delta$$

measure	objective
frequency synchronization	stability/min. skew
time synchronization	accuracy / min. offset

# When to re-synchronize ?

---

**Maximum drift rate  $\rho$ :**

$$1-\rho \leq dC/dt \leq 1+\rho$$

**constant  $\rho$  is a part of the physical clock specification; typical:  $10^{-5}$  to  $10^{-6}$**

**difference of two un-synchronized clocks  $\Delta t$ :**

$$\leq 2\rho\Delta t$$

**re-synchronization interval if two clocks should not deviate more than  $\delta$  seconds after**

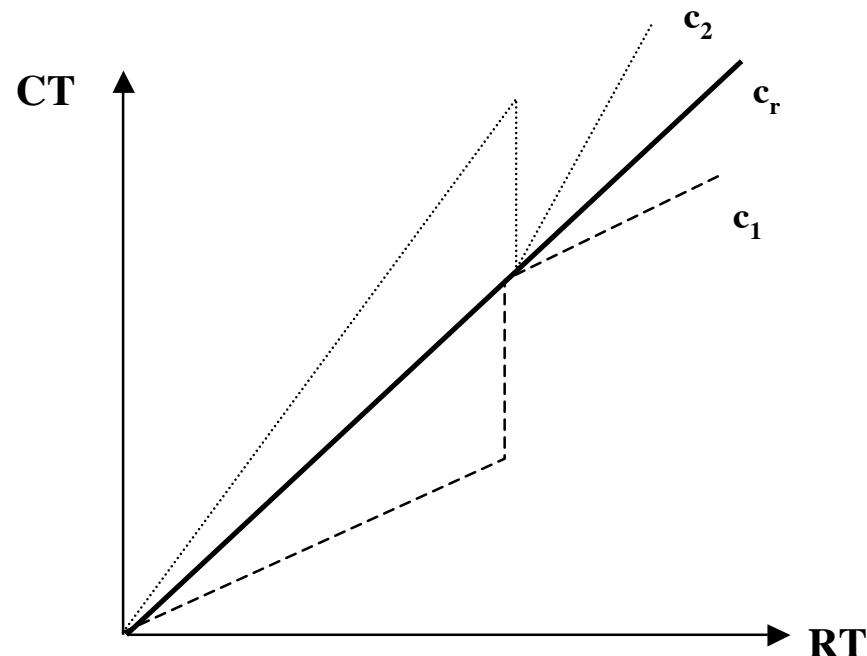

$\delta / 2\rho$  seconds

# How to synchronize ?

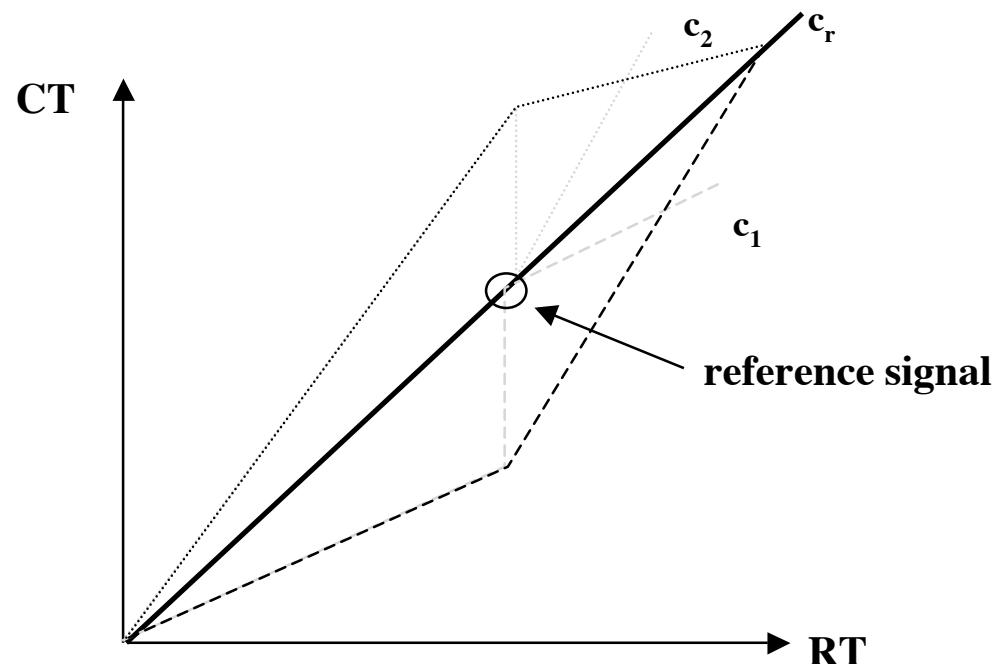

---

## Adapting clock values

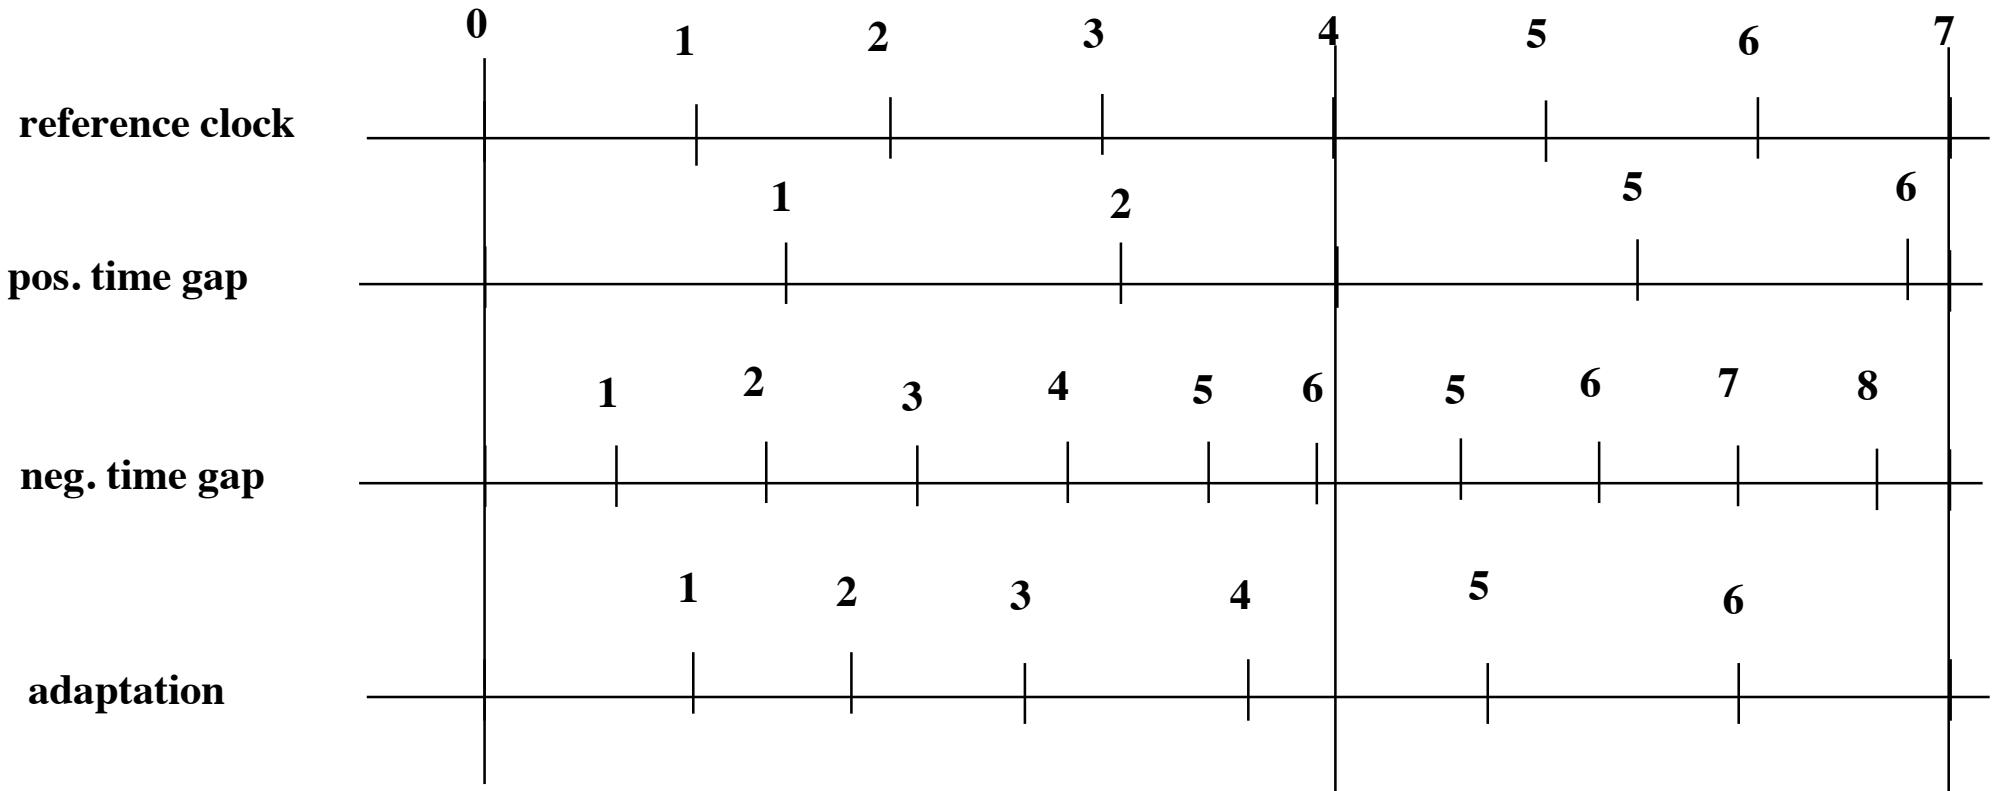

# How to synchronize ?

## Adapting clock rates

# How to synchronize ?

- counter correction
- drift correction

---

# Clock synchronization via messages in communication networks

- **time server**
- **Master- Slave synchronisation**
- **Decentralized and co-operative sync.**

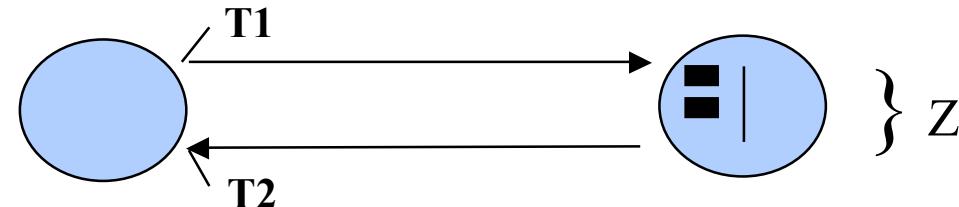

# Server-based clock synchronization

---

## Cristian's Algorithm:

Every node synchronizes its time base periodically with a time server.

period:  $\frac{\delta}{2\rho}$  to keep error below  $\delta$

- (a) send request for a time stamp  $Z$  to the time server
- (b) calculate a correction factor  $K$  to correct the local clock

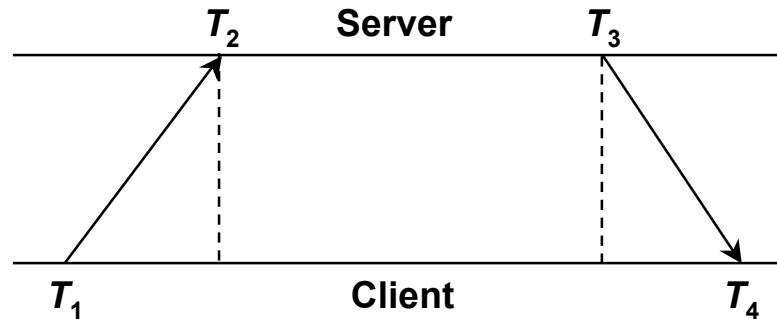

Problems:

- Monotony properties of timee
- Measurements are based on roundtrips ( $T_2-T_1$ ). A roundtrip may vary depending on network condidtions.
  - > simple correction:  $[(T_2-T_1)/2 - Z]$
  - > Refinement 1: statistical methods to calculate the average of  $T_2-T_1$ .
  - > Refinement 2: statistical methods to estimate the delay in the server.

# Calculating offset and delay

---

Offsets o  
Delay d

$$o = [(T_2 - T_1) + (T_3 - T_4)] / 2$$

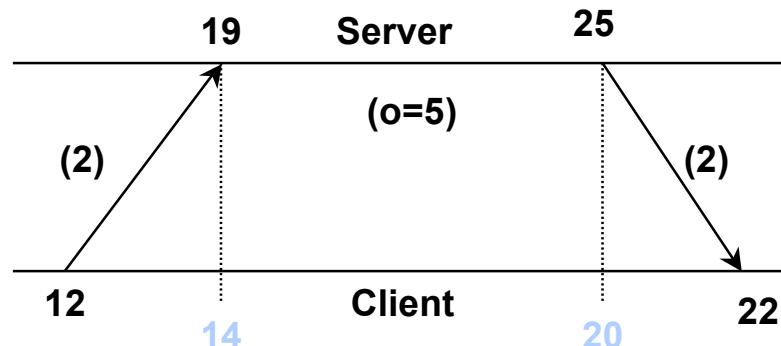

$$d = (T_4 - T_1) - (T_3 - T_2)$$

# Calculating offset and delay

---

Offsets o  
Delay d

$$o = [(19 - 12) + (25 - 22)] / 2$$
$$o = 5$$

$$d = (22 - 12) - (25 - 19)$$
$$d = 4$$

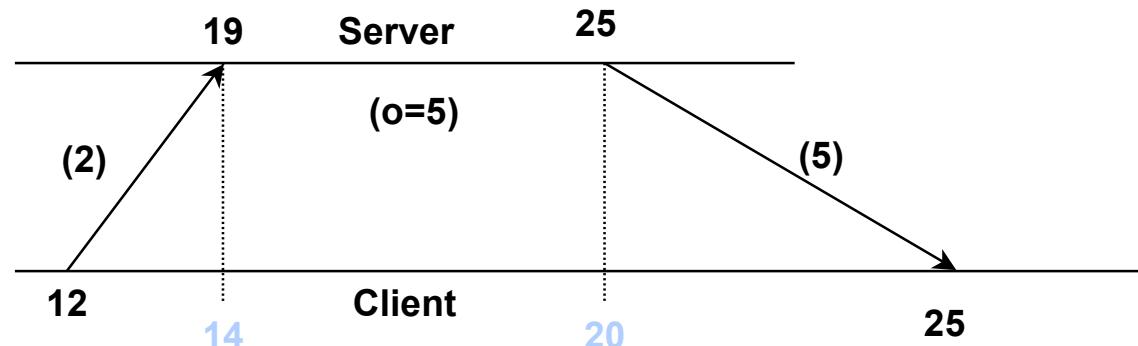

# Calculating offset and delay

---

Offsets: o

Delay: d

$$o = [(19 - 12) + (25 - 25)] / 2$$
$$o = 3,5$$

$$d = (25 - 12) - (25 - 19)$$
$$d = 7$$

# Parameter for the calculation of time

---

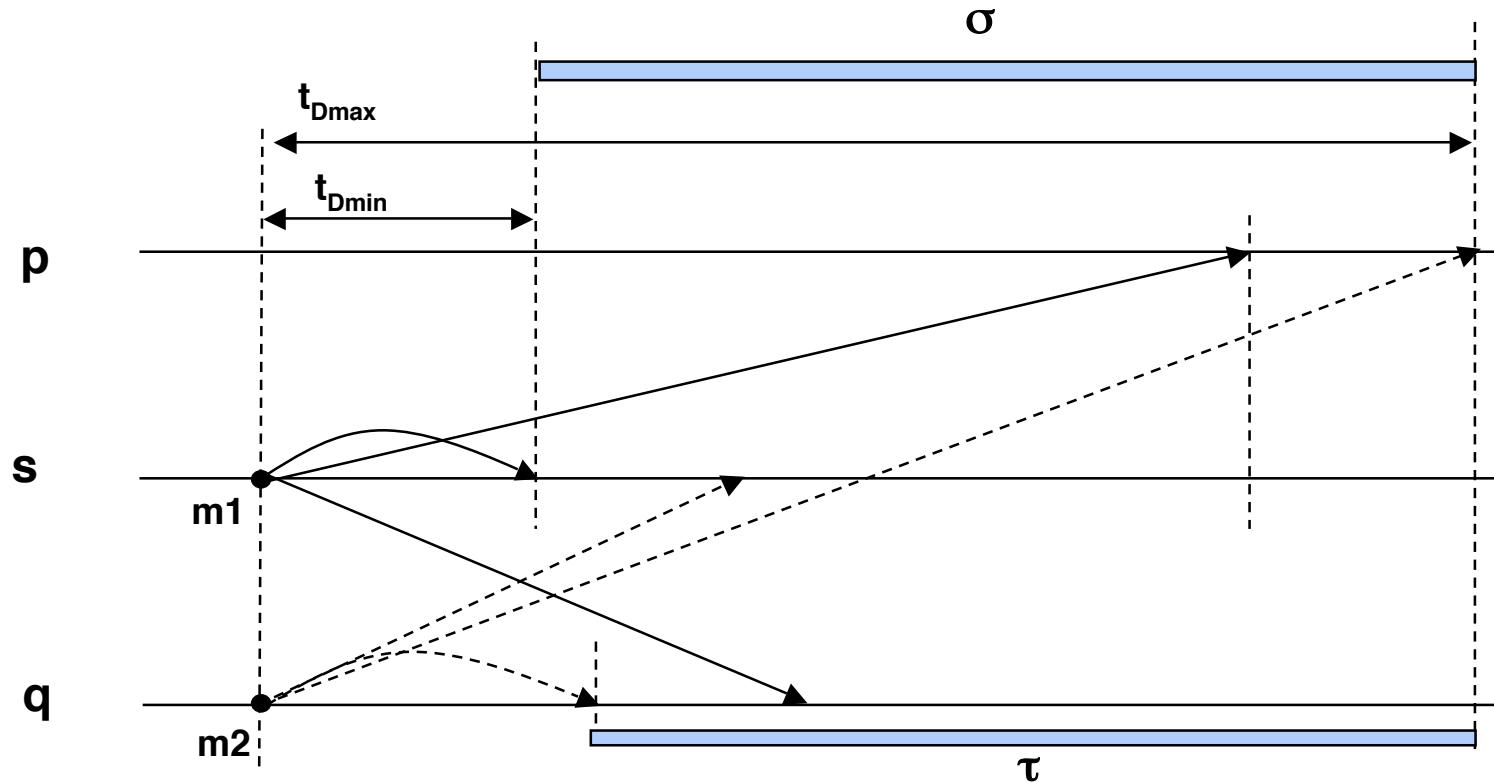

- message delays in the communication network  
**(steadiness + tightness)**
- Time until the message is sent  
Delays in the Reply Queue
- Delay when reading the local clock  
Delay in the Request Queue
- Physical parameters of the server clock:  
Drift, Offset

# Network Synchrony Properties

Steadiness  $\sigma$  : measures the maximal difference of delivery times of **DIFFERENT** messages.

Tightness  $\tau$  : measures the difference of transmission times of **ONE** message to **DIFFERENT** nodes.

# NTP Architecture, Protocol and Algorithms

David L. Mills  
University of Delaware  
<http://www.ee.udel.edu/~mills>

David L. Mills : „Internet Time Synchronization: The Network Time Protocol“, IEEE TC on Communications, 39(10), 1991  
<http://www.ee.udel.edu/~mills/ntp.html> (20.5.07)

# The *Network Time Protocol* (Internet NTP)

## Properties:

- Synchronization of physical time in LANs/WANs with UTC;  
Statistical techniques to:
  - consider the variance and delay of message transmissions
  - consider the quality of time on different time servers
- High availability by redundant servers and connections
- Scalability concerning the number of time servers, clients and the synchronization rate (adapted to Internet characteristics).
- Authentification of messages and time information to protect time services against manipulation

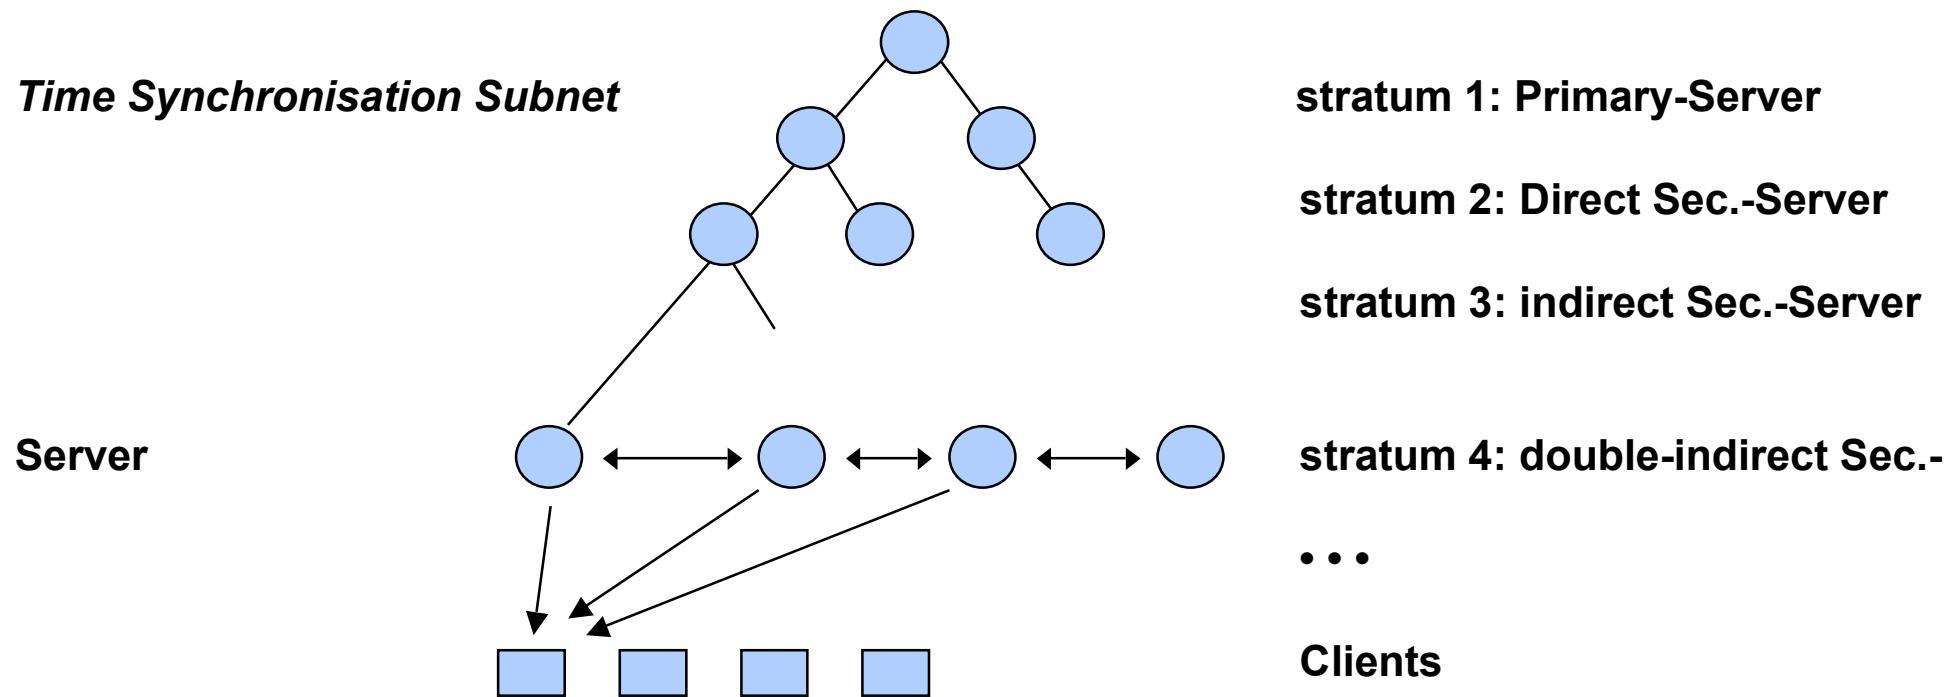

# The Network Time Protocol (Internet NTP)

## Hierarchy of time servers:

- Primary server: UTC-clock
- Secondary server: directly or indirectly connected with a primary server. May not have a UTC-clock.

## Time Synchronisation Subnet

# The *Network Time Protocol* (Internet NTP)

---

## Reconfiguration

- Clock failure in a primary server → server becomes secondary server

## Communication

- Cristian's algorithm: RPC-based communication, server send time-stamped replys
- on lower strati, symmetric relations between servers mutually exchanging time information
- in LANs: Multicast is used to distribute time information

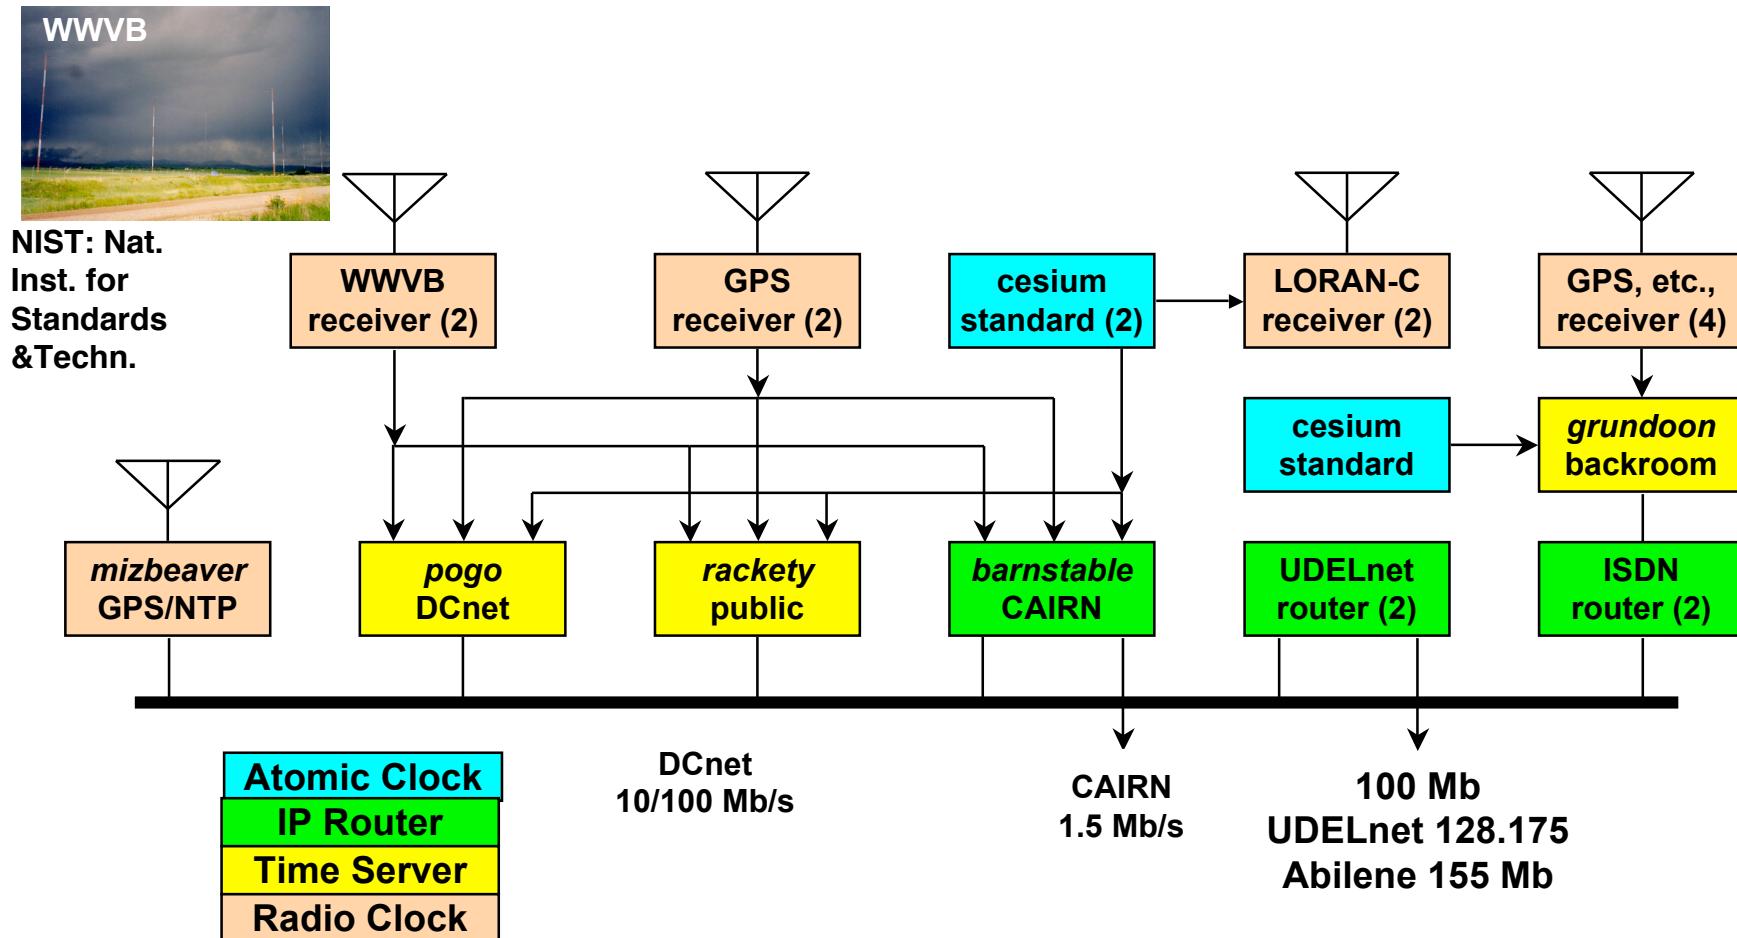

## High precision by exploiting the history of time messages:

Every server adds to the time message  $t_A$

- the time stamp when the last request  $r_L$  was received
- the time stamp when the corresponding reply  $t_L$  has been sent
- the time stamp when the actual message  $t_A$  has been sent

# DCnet timekeeping facilities (January 2001)

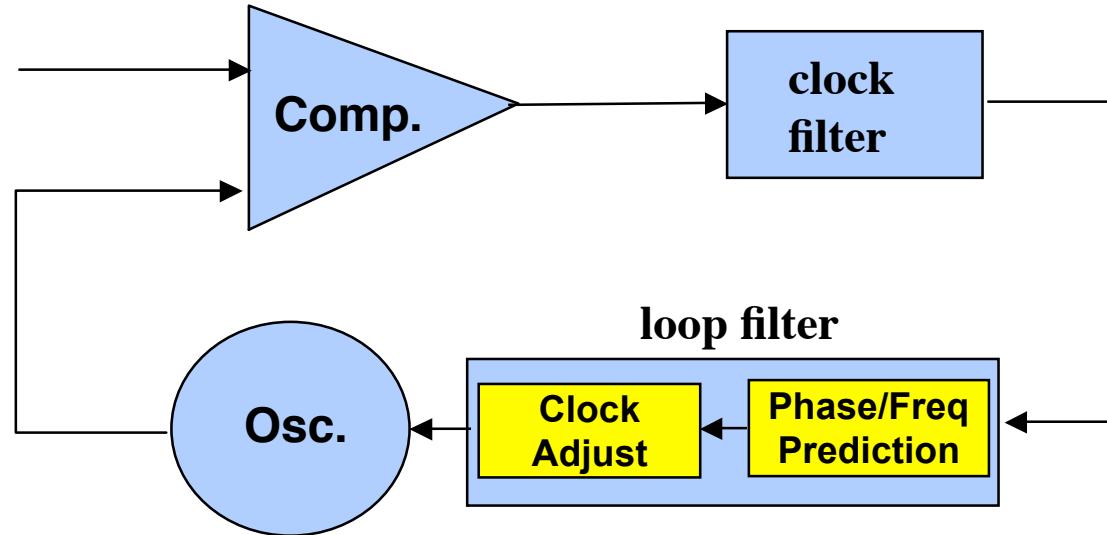

D. Mills/02

# PLL-Modell of NTP

---

NTP controls the "oszillator frequency"

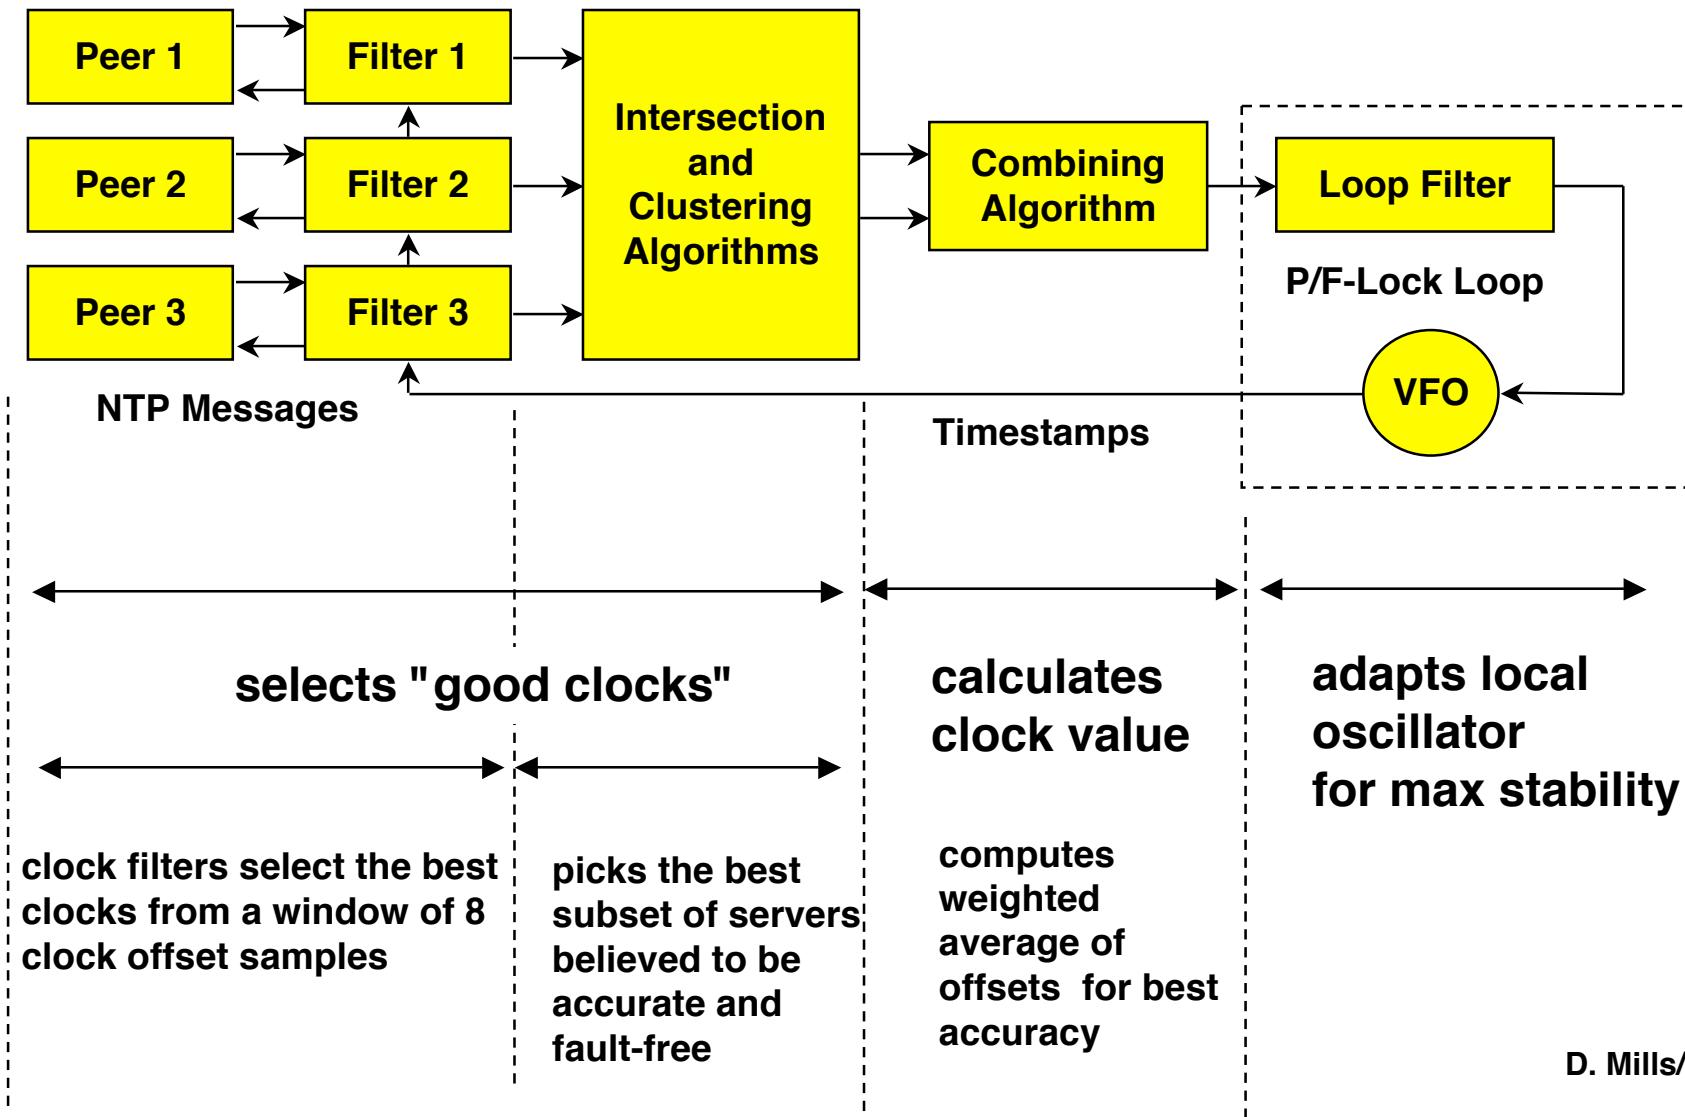

**clock filter:** selects appropriate time messages from the set of received time messages

**loop filter:** calculates the correction factor for the oszillator

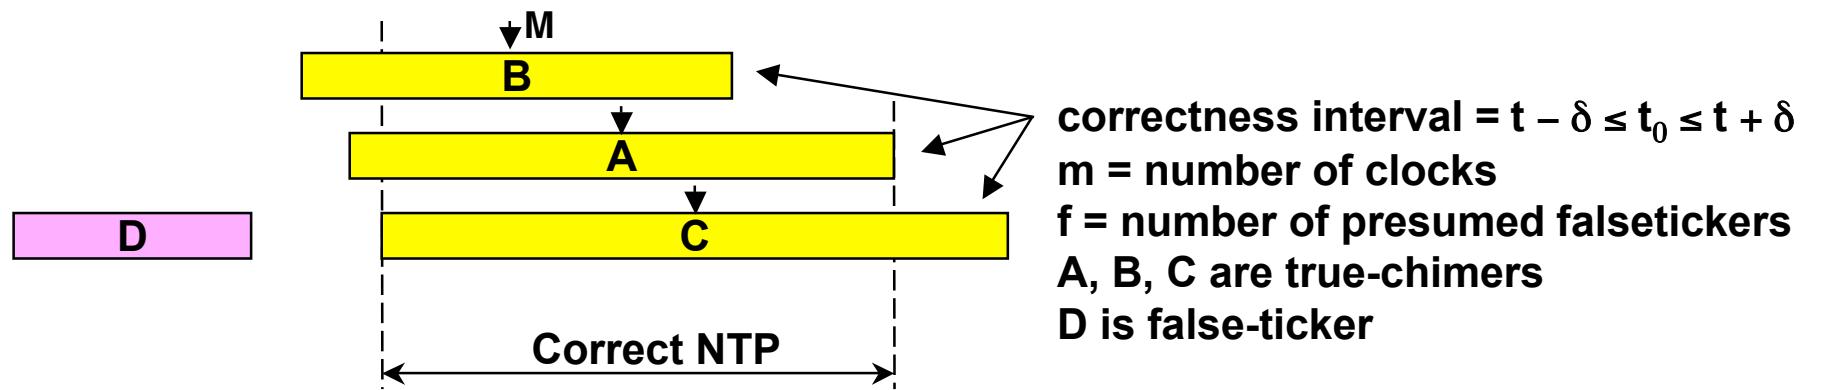

D. Mills/02

# How NTP works

# Intersection algorithm

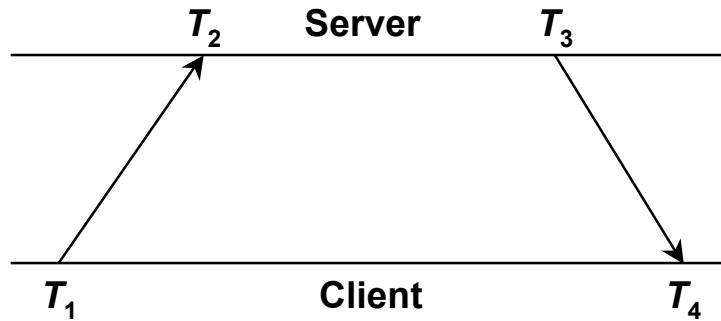

- NTP algorithm requires the *midpoint of the intervals* to be in the intersection
  - Initially, set falsetickers  $f$  and counters  $c$  and  $d$  to zero
    - Scan from far left endpoint: add one to  $c$  for every lower endpoint, subtract one for every upper endpoint, add one to  $d$  for every midpoint
    - If  $c \geq m - f$  and  $d \geq m - f$ , declare success and exit procedure
  - Do the same starting from the far right endpoint
    - If success undeclared, increase  $f$  by one and try all over again
    - if  $f \geq m/2$ , declare failure

D. Mills/02

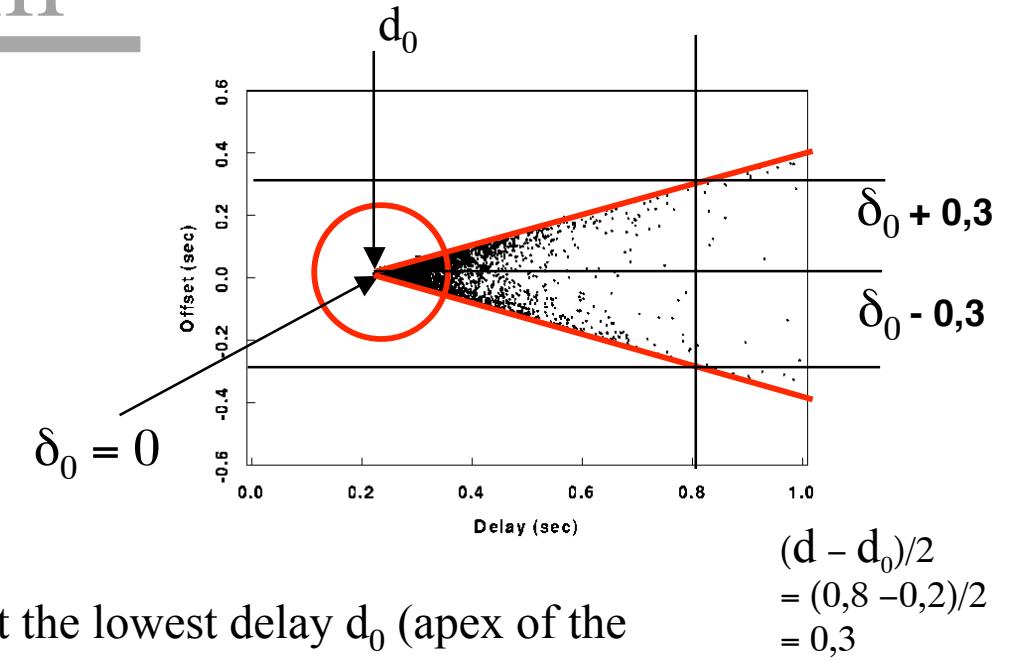

# Clock filter algorithm

$$\text{offset : } \delta = \frac{1}{2}[(T_2 - T_1) + (T_3 - T_4)]$$

$$\text{delay : } d = (T_4 - T_1) - (T_3 - T_2)$$

- The most accurate offset  $\delta_0$  is measured at the lowest delay  $d_0$  (apex of the wedge scattergram).
  - The correct time must lie within the wedge  $\theta_0 \pm (d - d_0)/2$ .
  - The  $d_0$  is estimated as the minimum of the last eight delay measurements and  $(d_0, \delta_0)$  becomes the offset and delay output.
  - Each output can be used only once and must be more recent than the previous output.
- The distance metric  $\lambda$  is based on delay, frequency tolerance and time since the last measurement.

D. Mills/02

# Fault-tolerant convergence algorithms:

---

- Fault-tolerant Midpoint and
- Fault-Tolerant Average

## – Fault-tolerant Midpoint:

The  $k$  largest and the  $k$  smallest values will not be considered.

The average is computed from the values  $k+1$  und  $n-k$ :

- Midpoint:  $(\text{max\_value} + \text{min\_value}) / 2$
- this is NOT the MEAN value of the sorted list of values!!!!

## – Fault-tolerant Average:

The  $k$  largest and the  $k$  smallest values will not be considered. The average will be computed from the remaining values.

# Time representation format in NTP

---

The time is the number of seconds since 00:00 (midnight) 1 January 1900

The maximum number that can be represented is  
**4,294,967,295 seconds** with a precision of about 200 picoseconds,  
which should be adequate for even the most exotic requirements.

1	2	3													
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1															
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+															
	Seconds														
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+															
	Seconds Fraction (0-padded)														
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+															

Note that, since some time in 1968 (second 2,147,483,648) the most significant bit (bit 0 of the integer part) has been set and that the 64-bit field will overflow some time in 2036 (second 4,294,967,296).

# NTP Packet Header

**LI** : Leap indicator, indicates a „leap second“ because of UT/UTC difference

## VN: Version number of NTP Impl.

**Mode:** Operational mode, e.g. client or server

## **Stratum:**

## 1: primary reference

## 2-15: secondary reference

## 16-255: reserved

**Poll: Max. interval between consecutive time messages.**

## Precision: precision of local clock

## Root Delay: Roundtrip Delay

**Root Dispersion: Statistical error relative to the primary reference**

**Ref. ID:** ID of the reference clock (e.g. DCF77)

## Ref.TS: time of last synchronization

**Originate, Rx. Tx.: Client req., Server Rx. Sever Tx to calculate roundtrip.**

**Authenticator:** for optional authentication of time stamps.

# Control characteristic

---

## Phase error

**100ms**

**corrected after 39 Min.**

**overshoot (overcompensation) 7ms after 54 Min.  
stabilizes to error < 1ms after 6h**

## Frequency error

**50 ppm**

**1 ppm after 16h**

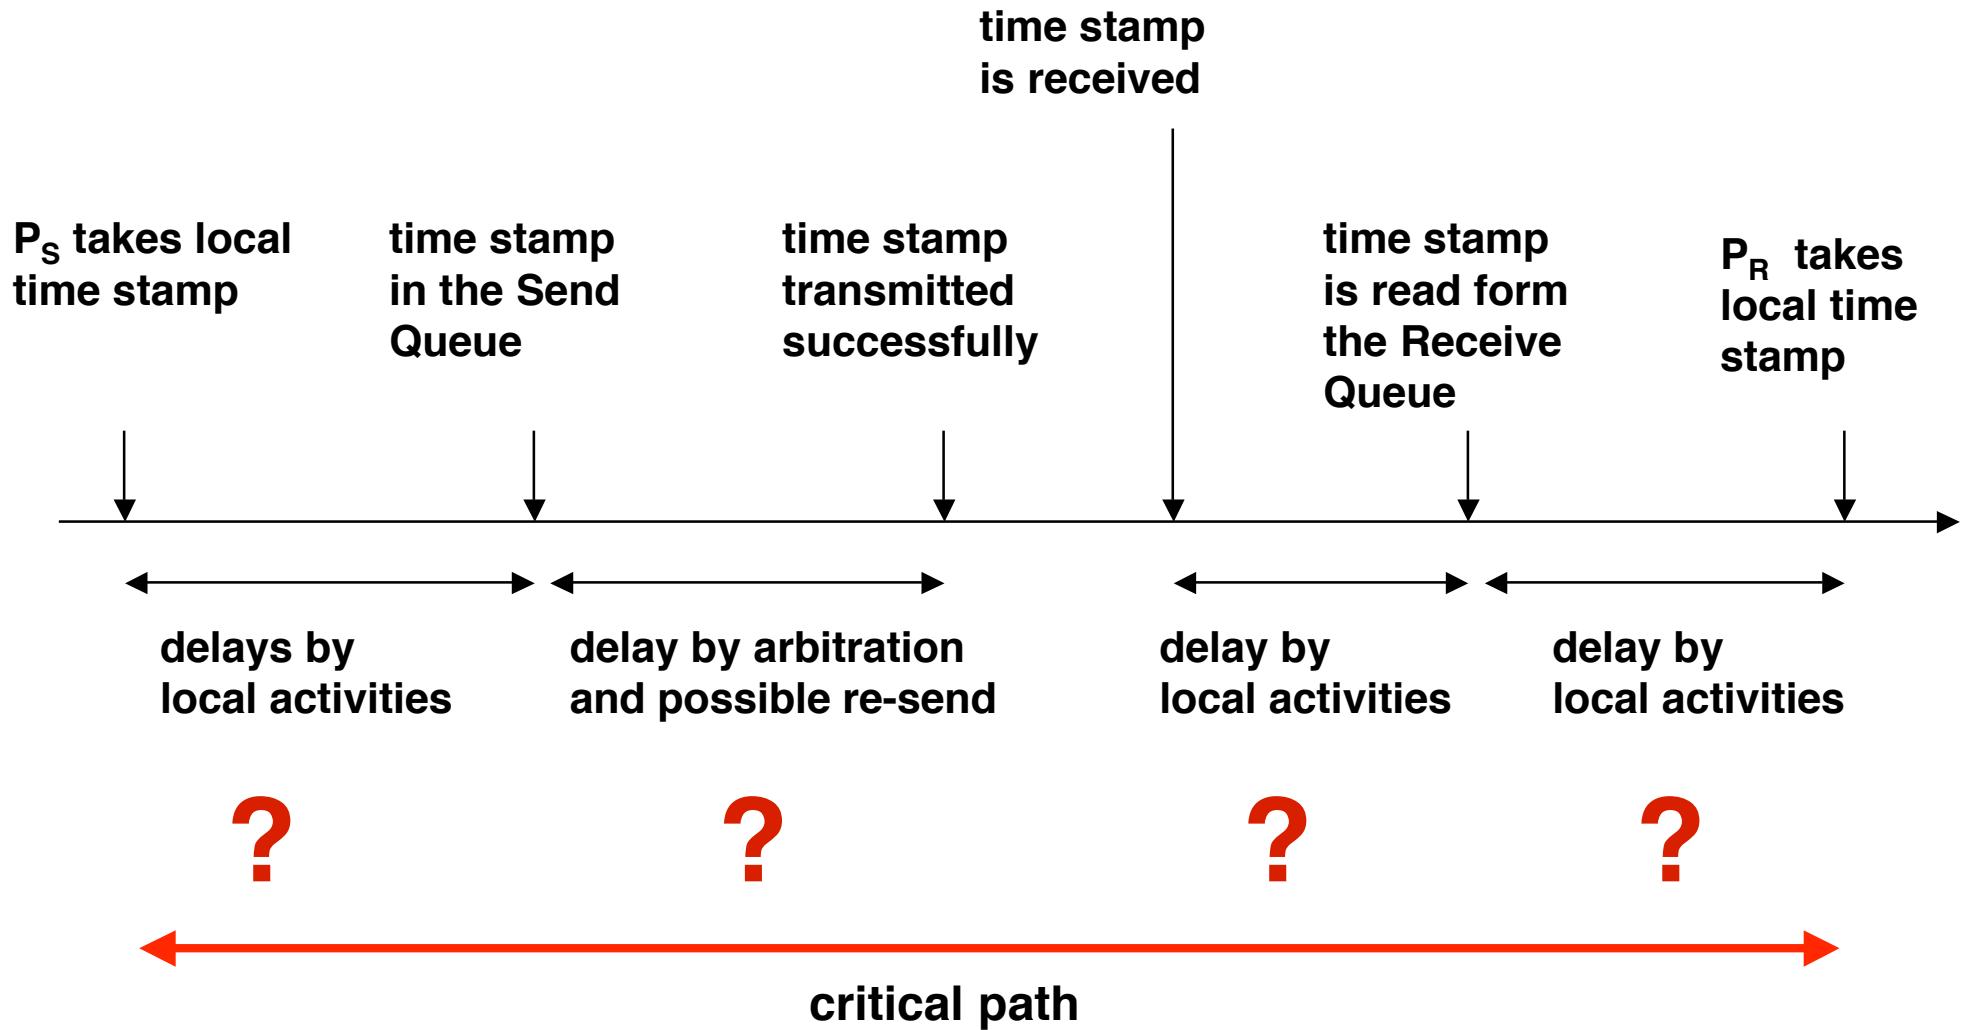

**0,1 ppm afterh 26 h**

**=> measurements: 99% of all time information deviates less than 30 msek from UTC.**

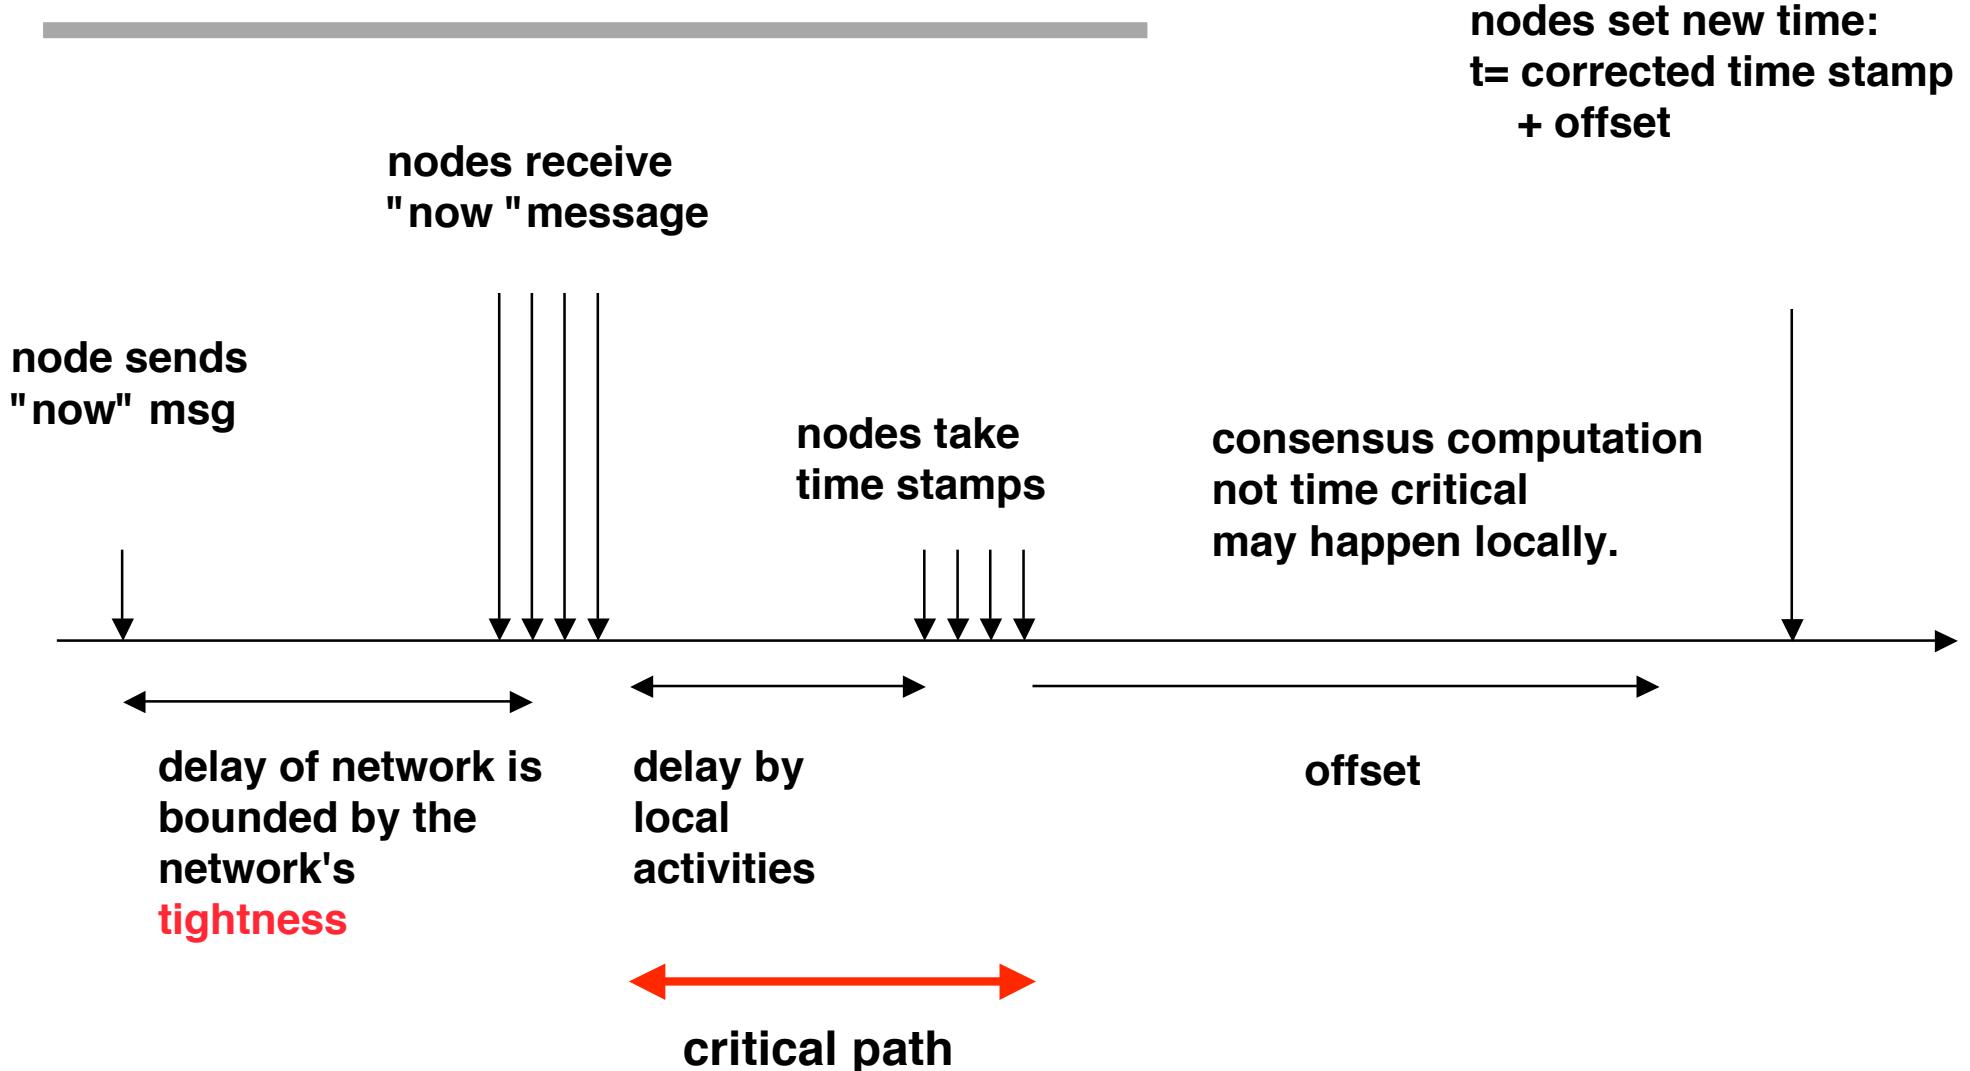

**If the clock is outside the capture of the PLL, the clock will be adjusted rather than the Oscillator frequency.**
